

Q.1)

An electric circuit works when electricity is produced by the bulb and travels through the wires to the battery. The battery stores electricity and provides it to the circuit.

The switch is used to increase or decrease the voltage in the circuit. When the switch is open, the current can flow because the circuit is complete.

The bulb is connected in parallel with the battery so that it can produce light. The resistor is used to increase the current flowing in the circuit. The ammeter is connected in parallel to measure current and the voltmeter is connected in series to measure voltage.

When resistance is increased, the current also increases because more resistance pushes more electricity through the wire.

Q No. 2

→ Technology has made learning easier because students can find almost everything on the Internet. However I think technology doesn't always make students learners. Many students simply search for answers instead of understanding the topic.

For example, if a student gets homework, they can search the exact questions online and copy the answer. This saves time but they may not learn anything. Techno

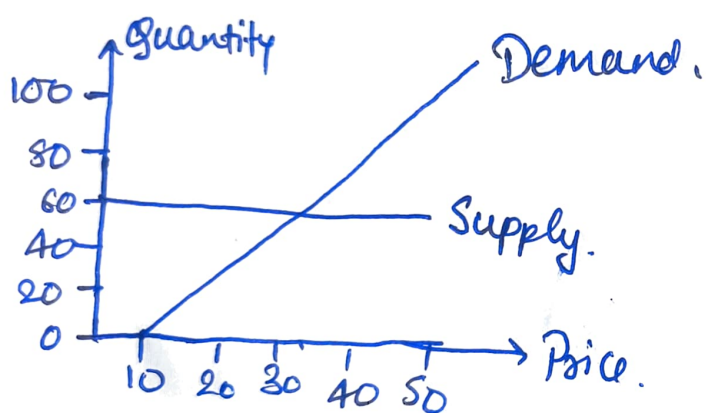

Some people believe Technology makes students more intelligent because they have access to much more information than students in the past. I disagree with this completely because having information does not mean that a person understands it.

In my opinion, technology is mostly making students dependent on easily available answers. Students should use books and teachers instead of depending too much on technology. Therefore, technology is not very useful for learning unless students use it carefully.

Q No 3

The graph shows that when the price increases, demand also increases. Supply also increases. Therefore, both demand and supply curves upward.

The equilibrium price is ₹30 because at this price the quantity demanded and quantity supplied are both 60.

When the price is below equilibrium, there will be excess supply because producers will supply more goods than consumers demand. When price is above equilibrium, there will be a shortage because consumers will demand more goods than producers supply.

If the cost of production increases, producers will be able to produce more goods because they will receive a higher price. Therefore, the supply curve will shift to the right and equilibrium quantity will increase.
